

# Simulations of IBS for Protons in 2012

**Michaela Schaumann**

Thanks to John Jowett, Roderik Bruce

# Collider Time Evolution (CTE) Program

---

- ▶ Authors: Roderik Bruce, Mike Blaskiewicz and Tom Mertens
- ▶ Program to track 2 bunches of **macro-particles** in time in a collider
  - ▶ Subroutines act on the bunches on a **turn-by-turn basis**: one simulation turn can correspond to any chosen number of machine turns.
  - ▶ Several other input parameter define the initial beams: e.g. particle type, particles per bunch, emittances in X und Y, bunch length, RF voltage...
  - ▶ IBS effects are simulated but no Beam-Beam

# Starting Conditions used in CTE Simulations

---

|                        |  | Unit                          | @ 450 GeV                | @ 4TeV              |
|------------------------|--|-------------------------------|--------------------------|---------------------|
| Emittance              | $\epsilon_{x,y}$                             | [um rad]                      | 1.9 / 2.0 /<br>2.2 / 2.5 | 2.0 / 2.5 / 3.0     |
| Intensity per<br>Bunch | Nb   | [10 <sup>11</sup><br>charges] | 1.5 / 1.6                | 1.6                 |
| Bunch Length           | $\sigma_t$ (4 $\sigma$ )<br>= 4 $\sigma_s/c$ | [ns]                          | 1.0 / 1.5                | 1.0 / 1.35 /<br>1.5 |

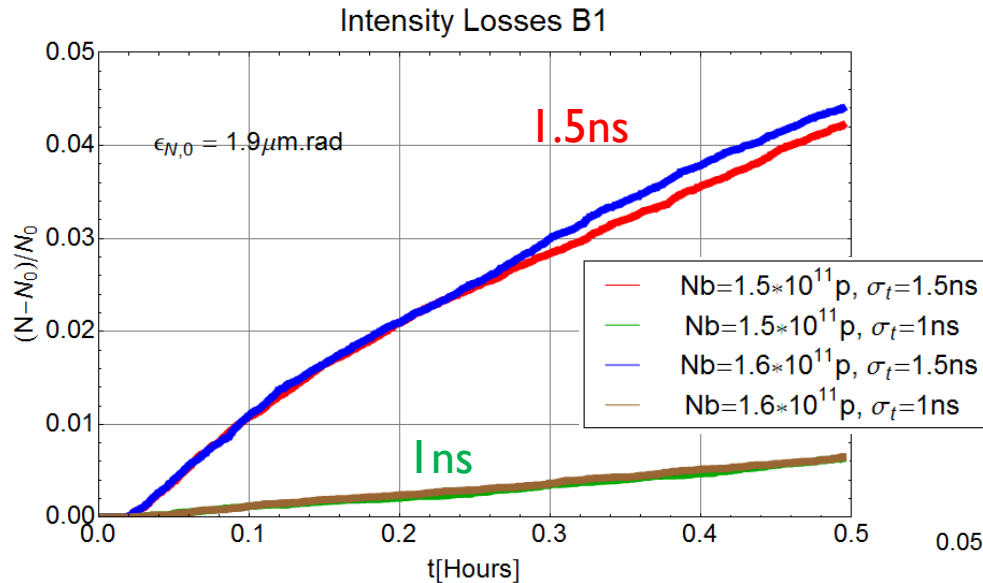

- ▶ Other important Settings
  - 6MV@inj, 12MV@4TeV RF-Voltage
  - round beams
  - uncoupled planes (for IBS growth)
  - beam shape: pseudo-Gaussian, exactly matched

---

# Injection

|                     |  | Unit                       | @ 450 GeV                        | @ 4TeV              |
|---------------------|--|----------------------------|----------------------------------|---------------------|
| Emittance           | $\epsilon_{x,y}$                             | [um rad]                   | <b>1.9 / 2.0 /<br/>2.2 / 2.5</b> | 2.0, 2.5, 3.0       |
| Intensity per Bunch | Nb   | [10 <sup>11</sup> charges] | <b>1.5 / 1.6</b>                 | 1.6                 |
| Bunch Length        | $\sigma_t$ (4 $\sigma$ )<br>= 4 $\sigma_s/c$ | [ns]                       | <b>1.0 / 1.5</b>                 | 1.0 / 1.35 /<br>1.5 |

# Intensity

## loss mechanisms

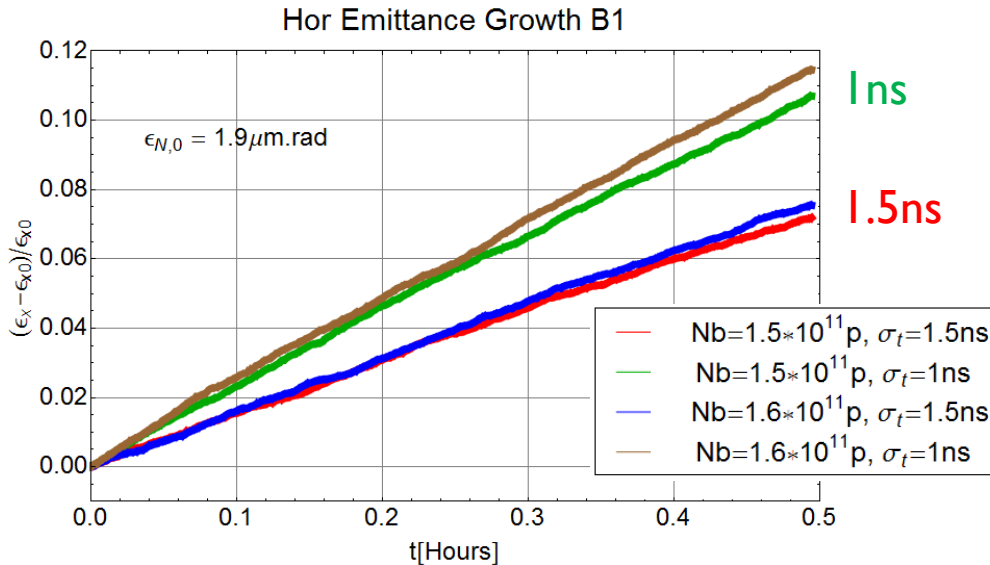

- ▶ particles leave bucket (debunching losses)
- ▶ hit physical aperture (due to dispersion or betatron action)

## ▶ highest losses for

- ▶ bunches with great bunch length (1.5ns)
- ▶ bunches with small emittance

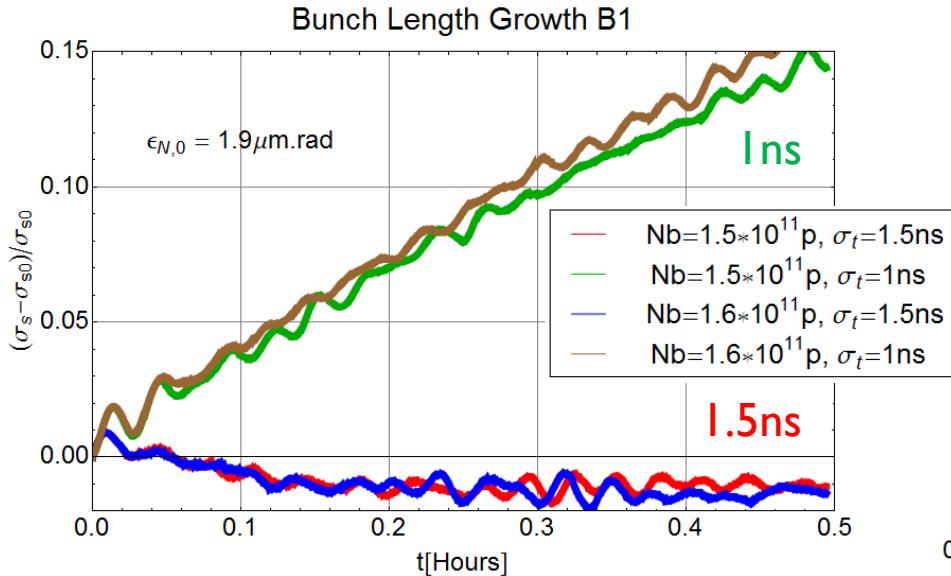

# Emittance

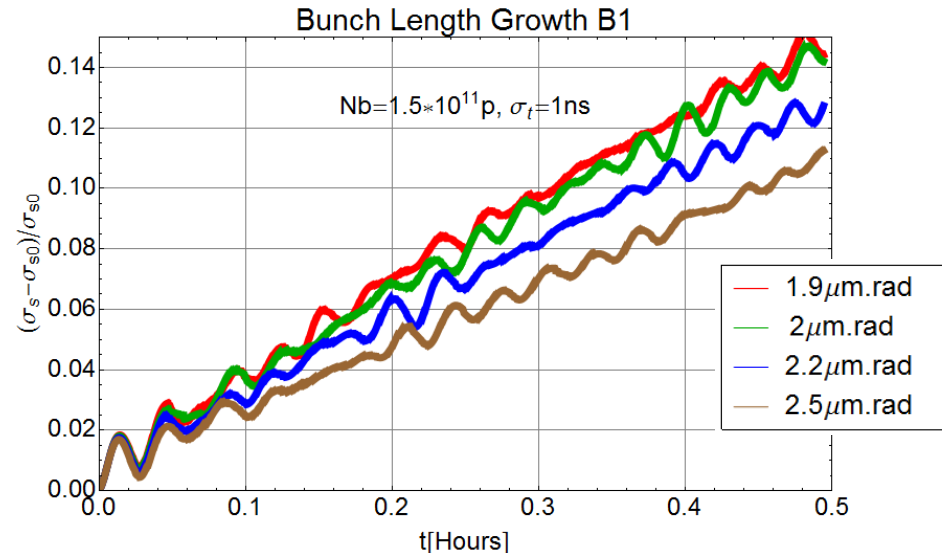

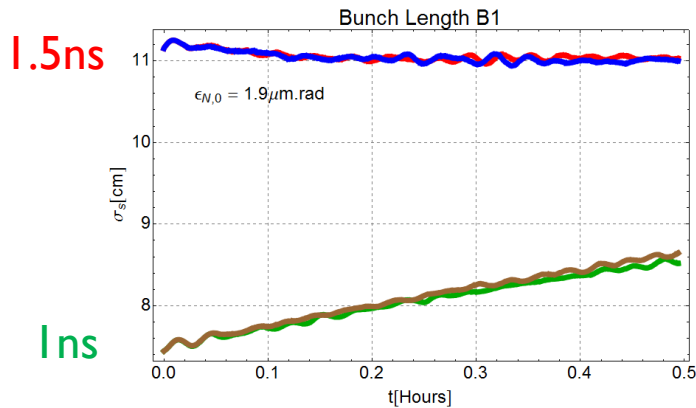

- ▶ small initial emittances increase faster
- ▶ small initial bunch lengths (1 ns) increase faster in transverse emittance
- ▶ no big difference for different initial intensities

# Bunch Length

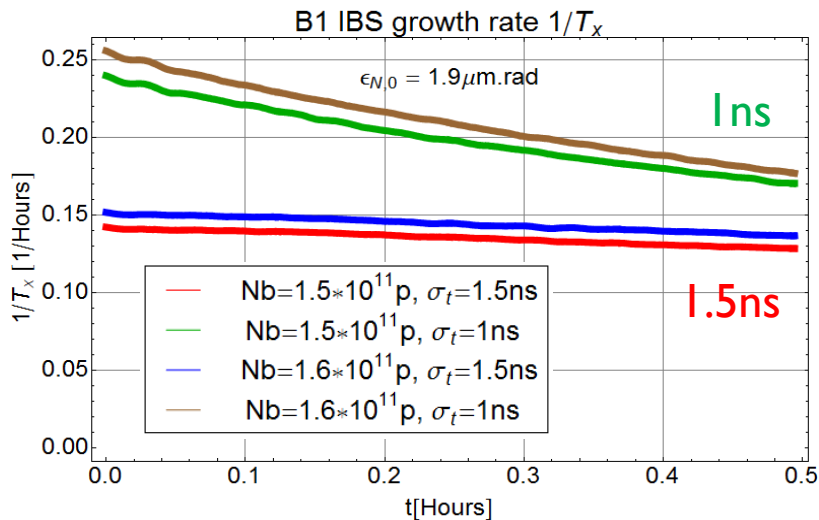

- ▶ small initial bunch lengths (1ns) grow much faster
  - ▶ particles fill the bucket
- ▶ 1.5ns case actually decreases a bit
  - ▶ tails of the distribution are cut when particles leave the bucket
  - ▶ RMS of the distribution decreases and Gaussian shape is lost

# IBS Growth Rates

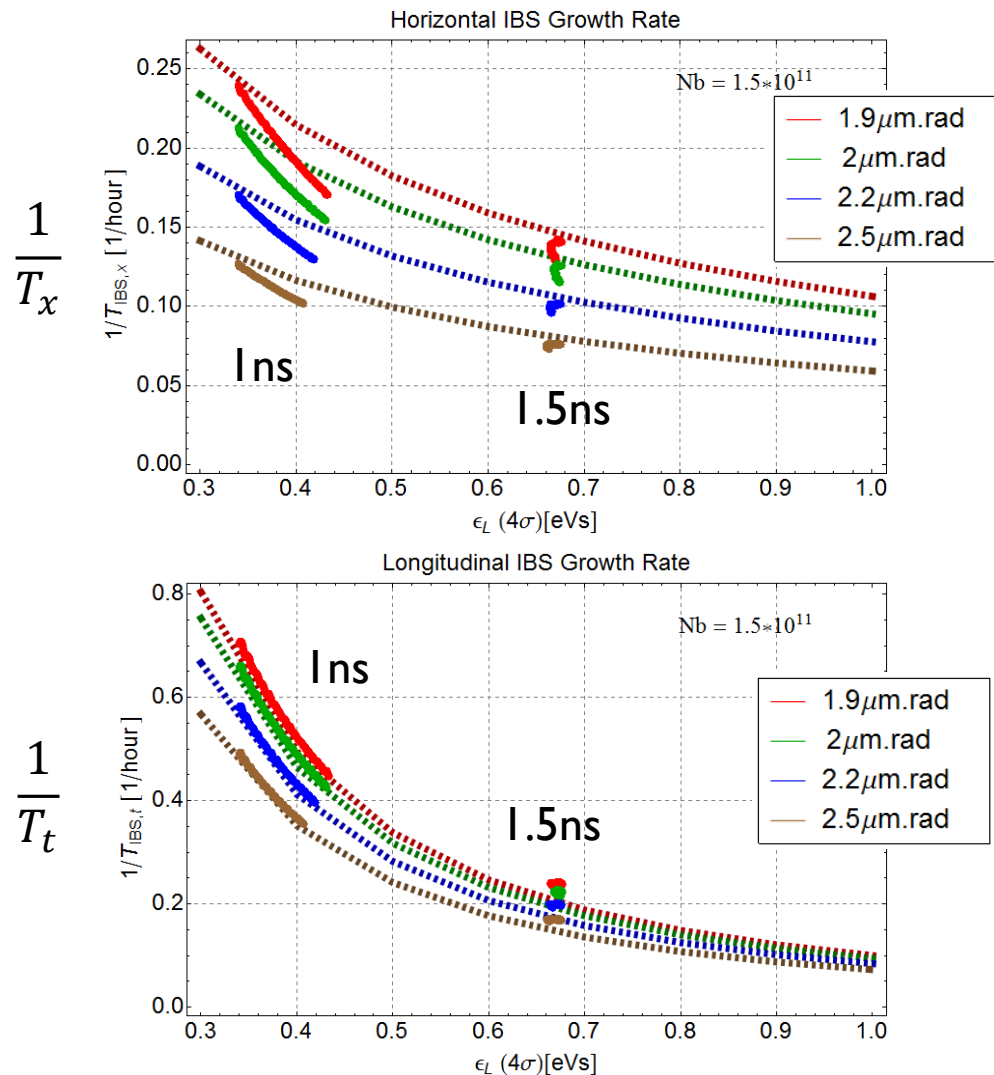

- ▶ 1ns growth rates start higher and decreases faster
  - ▶ emittances increase faster for small bunch lengths
- ▶ 1.5ns growth rates quite stable and much smaller as for 1ns initial bunch length
- ▶ initial growth rates increase with smaller initial emittances

# Comparison with MADX Calculations

## Growth Rate vs. Longitudinal Emittance

- ▶ MADX calculations are shown as the dashed lines
- ▶ Growth rate vs. longitudinal emittance  $\epsilon_L$ 
  - ▶ initial points in good agreement
  - ▶ lines separate for higher longitudinal emittances
  - ▶ MADX calculation only varies  $\epsilon_L$
  - ▶ in the simulation all parameters evolve with time
  - ▶ **only for initial points, both are expected to agree**

# Effect of injection conditions on Luminosity

**Figure of merit for initial luminosity vs. time spent at injection**

- ▶ calculate  $N^2 / \sqrt{\epsilon_x \epsilon_y}$  to get an estimate of what the luminosity would be if collisions were started
- ▶ curves for the 1 ns initial bunch length cases decrease slower
  - ▶ less intensity losses, since the particles fill the bucket before they start to get lost
- ▶ the high particle losses of the blown-up bunches decrease the expected luminosity much more, even if their emittance blow-up is slower
- ▶ a compromise for the blow-up of the longitudinal emittance has to be found, to optimize the initial luminosity (and luminosity lifetime later)

# Physics at 4TeV

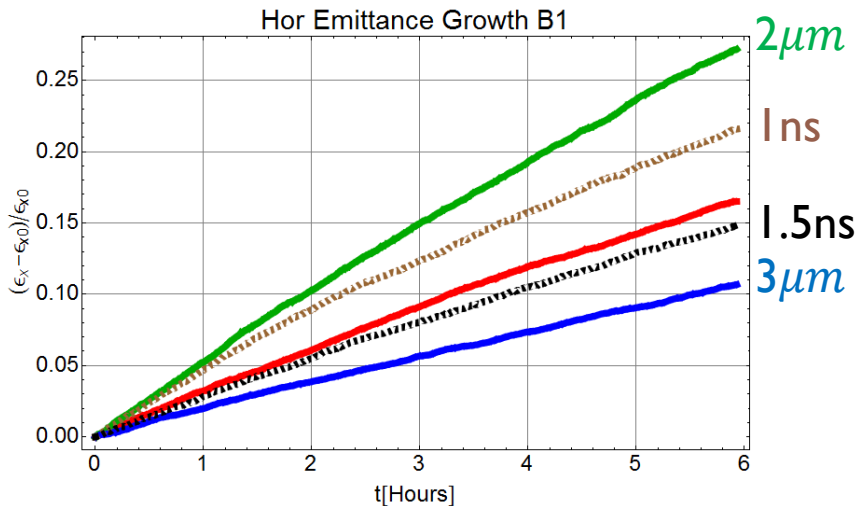

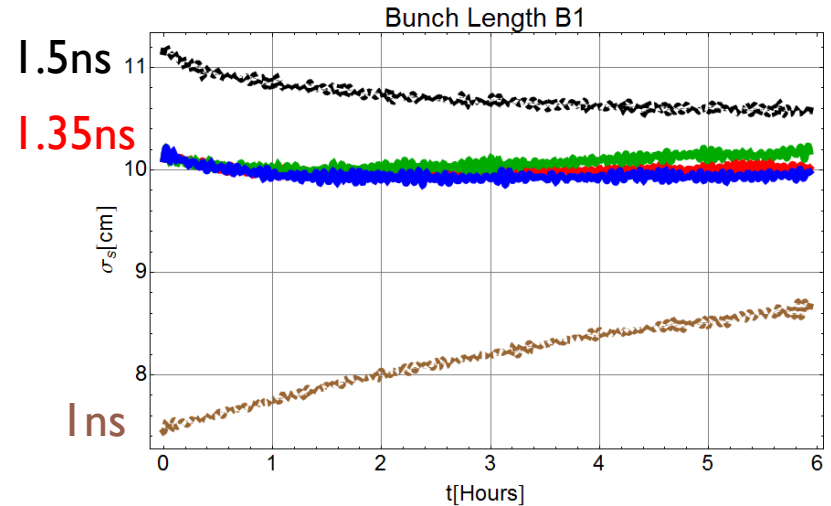

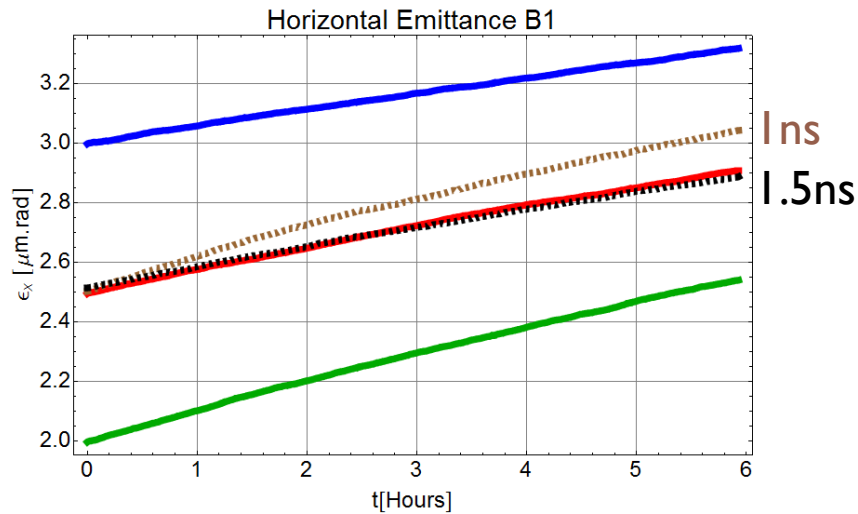

$$\begin{aligned} \varepsilon_N &= 2.5 \mu m \\ N_b &= 1.6 * 10^{11} \text{ ppb} \\ \sigma_t &= 1.35 ns = 10.1 cm \\ \beta^* &= 0.6 m \\ \frac{\theta_c}{2} &= 145 \mu rad \end{aligned}$$

Suggested Performance Reach for 50ns  
by G.Arduini in Charmonix 2012

|                     |  | Unit                       | @ 450 GeV                | @ 4TeV                      |
|---------------------|--|----------------------------|--------------------------|-----------------------------|
| Emittance           | $\varepsilon_{x,y}$                          | [um rad]                   | 1.9 / 2.0 /<br>2.2 / 2.5 | <b>2.0 / 2.5 /<br/>3.0</b>  |
| Intensity per Bunch | Nb   | [10 <sup>11</sup> charges] | 1.5 / 1.6                | <b>1.6</b>                  |
| Bunch Length        | $\sigma_t$ (4 $\sigma$ )<br>= 4 $\sigma_s/c$ | [ns]                       | 1.0 / 1.5                | <b>1.0 / 1.35 /<br/>1.5</b> |

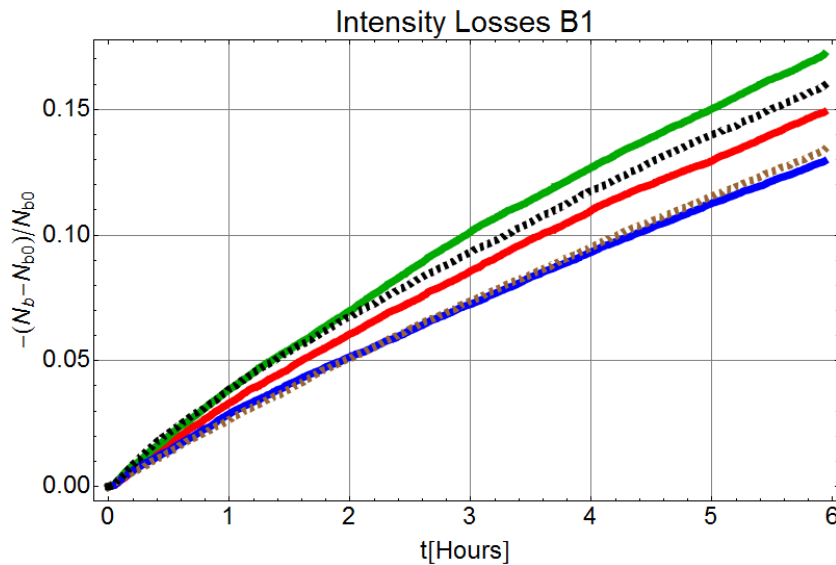

# Emittance and Bunch Length

|               |                             |
|---------------|-----------------------------|
| — (red)       | 1.6e11, 2.5 $\mu$ m, 1.35ns |
| — (green)     | 1.6e11, 2 $\mu$ m, 1.35ns   |
| — (blue)      | 1.6e11, 3 $\mu$ m, 1.35ns   |
| - - - (brown) | 1.6e11, 2.5 $\mu$ m, 1.0ns  |
| - - - (black) | 1.6e11, 2.5 $\mu$ m, 1.5ns  |

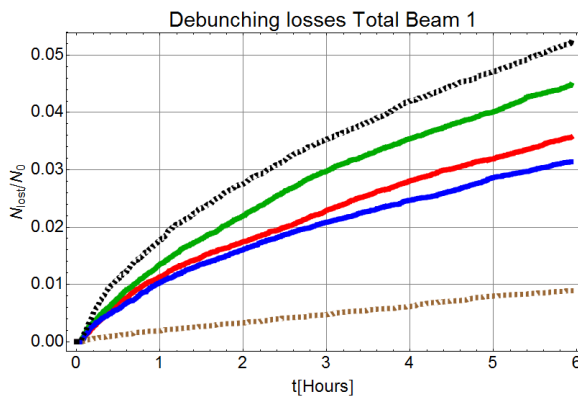

- ▶ small initial bunch length grow faster in transverse and longitudinal plane
- ▶ effect begins to saturate at 1.35ns
- ▶ smaller initial transverse emittances grow faster

# Intensity

- ▶ ~ 15% lost after 6h
- ▶ debunching losses differ significantly for different initial bunch lengths
- ▶ for greater bunch lengths the debunching losses become more important
- ▶ total losses dominated by luminosity burn off
- ▶ smaller transverse emittances lose more

# IBS Growth Rates

|                |                             |
|----------------|-----------------------------|
| — (red)        | 1.6e11, 2.5 $\mu$ m, 1.35ns |
| — (green)      | 1.6e11, 2 $\mu$ m, 1.35ns   |
| — (blue)       | 1.6e11, 3 $\mu$ m, 1.35ns   |
| - - - (orange) | 1.6e11, 2.5 $\mu$ m, 1.0ns  |
| - - - (black)  | 1.6e11, 2.5 $\mu$ m, 1.5ns  |

- ▶ same behaviour as at injection
- ▶ transverse and longitudinal beam size both have influence on each IBS growth rate
  - ▶ growth rates are higher for smaller beams
- ▶ for  $\geq 1.35$ ns initial bunch length the longitudinal growth becomes quite stable in time
- ▶ horizontal growth as well for  $\geq 2.5\mu$ m

# Luminosity

- ▶ bunch with smallest emittance has highest luminosity
- ▶ bunches with different initial bunch lengths show different initial luminosities
  - ▶ effect in agreement with the geometric luminosity reduction due to the crossing angle

$$F = 1 / \sqrt{1 + \left(\frac{\theta_c \sigma_z}{2\sigma_{xy}}\right)^2}$$

- ▶ 1.5ns case smallest luminosity – has highest debunching losses

# Conclusion

---

- ▶ Simulations were done for single bunch at injection and in physics.
- ▶ The beam conditions are shown as a function of time: this gives an estimate of the spread between early and late injected bunches.
  
- ▶ Higher initial bunch lengths blow-up the transverse and longitudinal plane slowly, but show high particle losses due to debunching.
- ▶ Small changes in the initial intensity do not have a significant effect at injection.
- ▶ The estimate of the potential luminosity at injection shows a great dependence on the losses due to debunching: the blow-up of the longitudinal emittance has to be optimised to find a compromise between smaller transverse emittance blow-up and higher particle losses.
  - ▶ Simulations in collisions show a tendency of the increased emittance blow-up to saturate around 1.3ns bunch length
  - ▶ Debunching losses become less important at higher energies – luminosity burn off dominates
  
- ▶ The IBS growth rates decrease fast with increasing bunch length and emittance
- ▶ The calculations of MADX and CTE are in good agreement for the initial parameters.

---

# BACK- UP

# Collider Time Evolution (CTE) Program

---

Processes taken into account:

## ▶ COLLISIONS

- ▶ user can choose between 2 collision routines:
  - ▶ very slow, integrates interaction probability for every particle by sorting particles in opposing beam in discrete bins. **No assumptions on the shape of the beam distribution.**
  - ▶ fast routine, **assumes Gaussian transverse distribution** and calculates interaction probability from transverse distribution analytically and uses **global reduction factor** (hourglass and crossing angle) for all particles. **No assumptions on longitudinal distribution.**

## ▶ IBS

- ▶ rise time calculated using a standard method and modulated to account for non-Gaussian longitudinal profiles
- ▶ user can choose between the following methods:
  - ▶ Nagaitsev full lattice
  - ▶ smooth lattice Piwinski
  - ▶ full lattice Piwinski
  - ▶ full lattice modified Piwinski
  - ▶ full lattice Bane (*not good at injection*)
  - ▶ interpolation from tabulated risetimes in external file at given points in emittance-space

## ▶ BETATRON MOTION

## ▶ SYNCHROTRON MOTION (particles outside RF bucket are lost)

## ▶ RADIATION DAMPING and QUANTUM EXCITATION

## ▶ transverse aperture cut from COLLIMATION

# Collider Time Evolution (CTE) Program

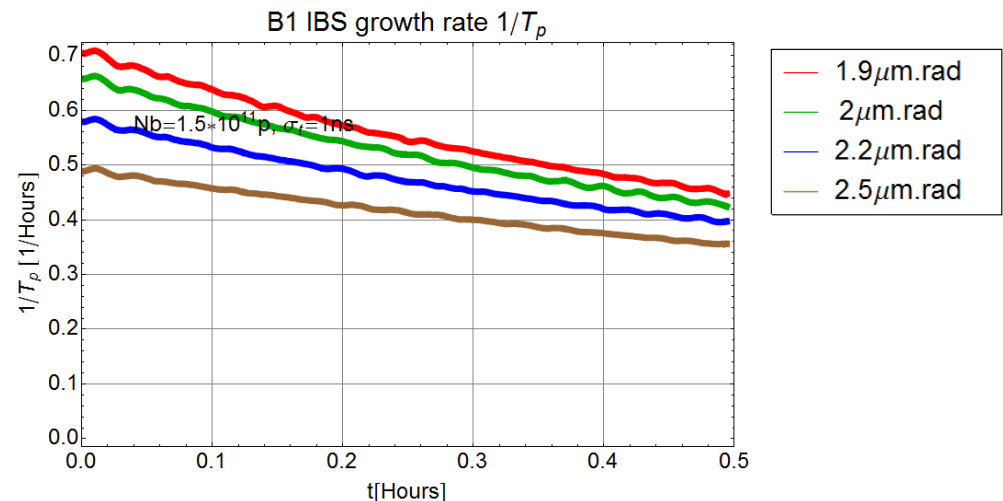

---

- ▶ **Output on a turn-by-turn basis**
  - ▶ IBS rise times
  - ▶ Intensity
  - ▶ Transversal and longitudinal emittances
  - ▶ Luminosity
  
- ▶ **Not Implemented**
  - ▶ Beam-Beam effects
  - ▶ Betatron noise from feedback
    - ▶ emittance blow-up
  - ▶ RF noise
  - ▶ Elastic and inelastic beam gas scattering
    - ▶ particle loss and emittance blow-up

# Longitudinal IBS Growth Rates

- ▶ 1ns growth rate starts higher and decreases faster
  - ▶ bunch length grows faster
- ▶ 1.5ns growth rate quite stable and much smaller as for 1ns initial bunch length
- ▶ initial growth rate increases with smaller initial emittances

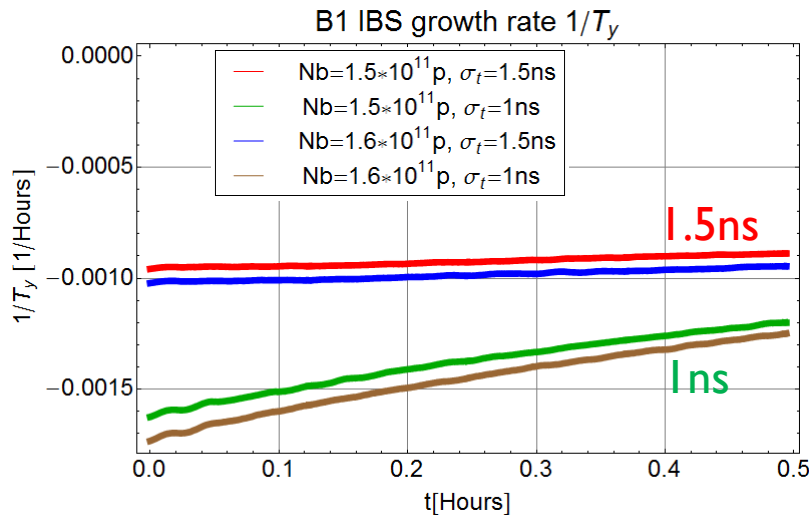

# Horizontal IBS Growth Rate

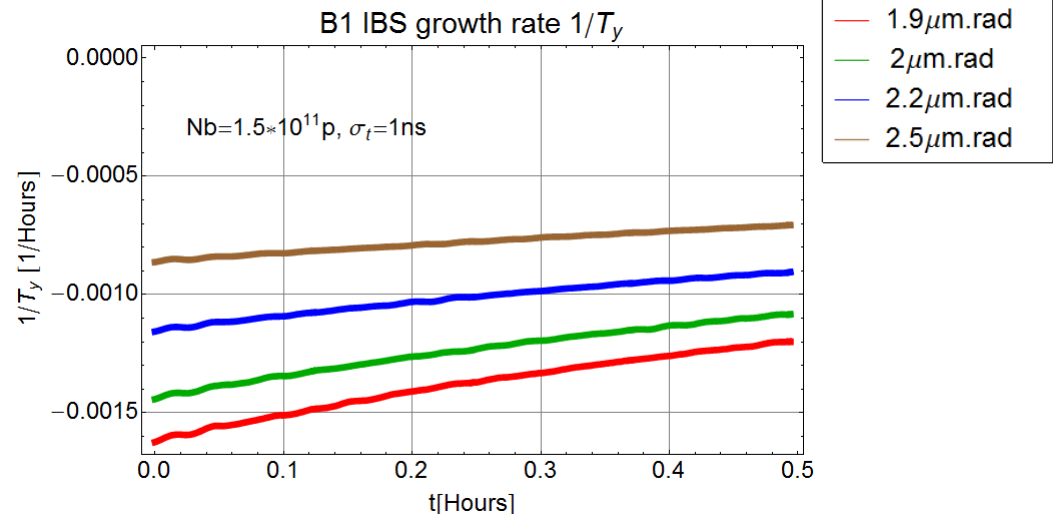

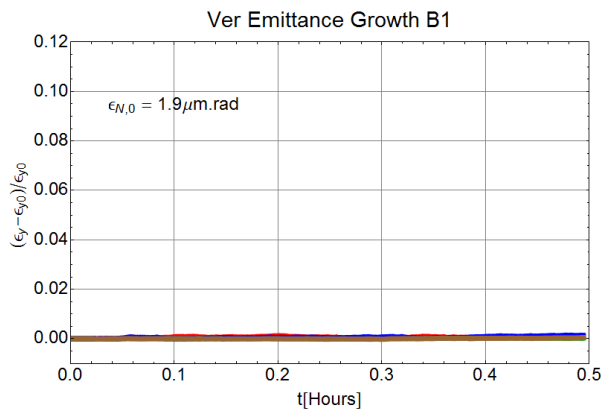

- ▶ same picture as for the longitudinal growth rate, but lower amount
- ▶ 1ns growth rate starts higher and decreases faster
  - ▶ horizontal emittance growth faster
- ▶ 1.5ns growth rate quite stable and much smaller as for 1ns initial bunch length
- ▶ initial growth rate increases with smaller initial emittances

# Vertical IBS Growth Rate

- ▶ Simulation was done for uncoupled transverse planes
- ▶ vertical growth rate very small and negative
- ▶ vertical emittance shrinks very slowly due to IBS

# Comparison with MADX Calculations Growth Rate vs. Transverse Emittance

# Simulation with HL-LHC Parameters

| Spacing: Nb, $\epsilon_{xy}$ , $\sigma_t$ |                                |
|---|--------------------------------|
| — (red)                                   | 25ns: 2e11, 2.5 $\mu$ m, 1.5ns |
| — (green)                                 | 25ns: 2e11, 2.5 $\mu$ m, 1ns   |
| — (blue)                                  | 50ns: 3.3e11, 3 $\mu$ m, 1.5ns |
| — (brown)                                 | 50ns: 3.3e11, 3 $\mu$ m, 1ns   |

- ▶ same picture as for 2012 parameters
- ▶ different bunch lengths have big effect on the evolution
- ▶ **small initial bunch lengths lead to faster growth in transverse and longitudinal plane**
- ▶ combination 3.3e11 ppb/3 $\mu$ m (50ns) and 2e11/2.5 $\mu$ m (25ns) only show small differences for equal initial bunch length
- ▶ only one bunch was simulated

# Simulation with HL-LHC Parameters (2)

| Spacing: $N_b$ , $\epsilon_{xy}$ , $\sigma_t$ |   |
|---|---|
| —   | 25ns: $2e11$ , $2.5\mu\text{m}$ , 1.5ns |
| —   | 25ns: $2e11$ , $2.5\mu\text{m}$ , 1ns   |
| —   | 50ns: $3.3e11$ , $3\mu\text{m}$ , 1.5ns |
| —   | 50ns: $3.3e11$ , $3\mu\text{m}$ , 1ns   |

- ▶ higher initial bunch lengths lose more particles
- ▶ particle losses affect the potential luminosity more than smaller emittance growth
- ▶ **luminosity decreases faster for higher initial bunch length**
- ▶ a compromise has to be found for the longitudinal blow-up to optimise the luminosity lifetime
